MediMesh: English Presentation Script

Design Round | Problem Statement 38 | Team Pixel Minds | About 7 minutes

Slide 1: Title (20 sec)

"Good morning, judges. We are **Pixel Minds**, and our project is **MediMesh**, a virtual warehouse for local pharmacies. Our domain is Software and Web Development."

Slide 2: Problem Statement (30 sec)

"Our problem is Statement 38, and it has two parts. First, customers often cannot find a medicine at their preferred pharmacy. Second, pharmacies have limited stock and must manage incoming requests efficiently."

"Our focus, in one line: **medicine access that does not fail when stock runs short.**"

Slide 3: Understanding the Problem (1 min)

"**Who is affected?** Patients and caregivers, especially those with urgent or chronic needs, and local chemists who work with limited stock."

"**What is going wrong?** When the preferred pharmacy is out of stock, the customer calls or visits shop after shop. The chemist has no system to manage this, so they either lose the sale or promise the same stock to two people. That is overselling."

"**Why does it matter?** A delay in medicine means a delay in treatment. For chemists, it means lost sales and expired dead stock. And today, realtime cloud tools are cheap and accessible, so building this network is finally practical."

Slide 4: Our Proposed Solution (1.5 min)

"In one line: we help customers get their medicines by routing each request across nearby pharmacies, with stock-safe reservation, instead of searching shop by shop."

"Here is how it works. **Step one, input:** the customer enters just the medicine and quantity, for example, Paracetamol, 10 strips."

"**Step two, process:** our system sends the request to nearby pharmacies and **soft-locks** the stock at a pharmacy that has it. If the preferred pharmacy does not have it, we borrow from a peer pharmacy. A soft-lock works like seat locking on BookMyShow: the stock is held for 30 minutes."

"**Step three, outcome:** the customer sees live status updates and collects the medicine at the counter."

Slide 5: Key Features (1 min)

"We have six key features, and each one maps to a pain point."

- "**Soft-lock Reservation** stops two customers from clashing over the last strips, so there is no overselling."
- "**Smart Matching** scores nearby pharmacies and tries the top three first, so requests rarely fail."
- "**Auto-Borrow and Ledger** pulls stock from a peer pharmacy and records the settlement automatically."
- "**Split Fulfilment** handles the case where the quantity exceeds stock, by splitting across pharmacies or fulfilling part of the order."
- "**Live Status Tracking** shows Requested, Sourcing, Confirmed and Ready to both the customer and the pharmacy."
- "**Lost Sales Meter** shows chemists how much they lose to stockouts and when to restock. That gives pharmacies a real reason to join."

"Together, these cover all three edge cases in the problem statement."

Slide 6: Architecture & Tech Stack (1 min)

"We use three layers. The **user layer** has the customer app, the pharmacy dashboard and a live map."

"The **application layer** holds the matching, soft-lock and borrow logic, built with Next.js API routes and Postgres functions, so the lock and the stock deduction happen in one atomic transaction."

"The **data layer** is Supabase Postgres for inventory, requests and the ledger, with Supabase Realtime for live status updates."

"Our stack is Figma for design, Next.js with Tailwind for the frontend, and Leaflet for maps. These are all free-tier tools, which makes this buildable within the 24-hour hackathon."

Slide 7: Innovation & Differentiation (1 min)

"On **ease of use**, customers today check shop by shop. With us, one request is enough, and the system finds and reserves the stock."

"On **cost and access**, most solutions are chain-focused. We are built for local chemists, with a small per-order fee."

"On **personalization**, the customer keeps their preferred pharmacy, and urgent cases get priority."

"On **scalability**, we benefit from a network effect: the more pharmacies join, the fewer stockouts."

(Pause here.) "Our unique edge is **peer-to-peer stock borrowing**, so that no request fails."

Slide 8: Impact, Feasibility & Risks (1 min)

"**Impact:** customers avoid multi-shop hunts, and chemists recover sales they would have lost."

"**Feasibility:** the core flow is buildable with Next.js and Supabase within 24 hours, and we will demonstrate a working flow from search to status tracking."

"**Scalability:** we grow locality by locality, starting with one area."

"**Risks:** the biggest risks are prescription medicines and logistics. Prescription-only medicines will proceed only after pharmacist verification, and we will start with a pilot in a single locality."

Closing (10 sec)

"We do not solve the problem of **finding** medicines. We solve the problem of **getting** them. Thank you, and we are happy to take your questions."

Q&A: ready answers

Question	Answer
How will delivery or runners work in reality?	"In the demo, the status is simulated. In practice, we would use local delivery partners or pharmacy-to-pharmacy runners, starting with a pilot in one locality."
What if a substitute suggestion is wrong?	"It is only a suggestion. It appears after pharmacist approval, with a disclaimer in the UI."
Why would a chemist join?	"The Lost Sales Meter shows the cost of stockouts in rupees, and the network brings them extra sales."
How are you different from 1mg or PharmEasy?	"They are delivery and e-commerce platforms. We are an inventory-sharing network among local chemists."

Speaking tips

- Give the most emphasis to slide 4 and slide 7, because that is your idea and your edge.
- Do not read from the slides. Glance at the key words and speak.
- The total is about 7 minutes, so practice 2-3 times with a timer.
